

The Solar-System Problem at a Glance

1. What is observed?

Only the sky as seen from Earth

The observed motions look very different.

2. What must the model do?

Compress, evolve, and predict

$t_0 \rightarrow t_1 \rightarrow t_2 \rightarrow \dots t_{49}$

Goal: predict both Earth-view angles at every weekly time step.

3. What simple state emerges?

Sun-centered coordinates

ϕ_E and ϕ_M advance at constant rates

The learned 2D latent is a linear combination of these heliocentric angles.

Key idea: a complicated Earth-view signal becomes simple, constant motion in heliocentric coordinates.
